Comparison with “random graph” used to determine whether real-world network is “small world”

Network	size	av. shortest path	Shortest path in fitted random graph	Clustering (averaged over vertices)	Clustering in random graph
Film actors	225,226	3.65	2.99	0.79	0.00027
MEDLINE co-authorship	1,520,251	4.6	4.91	0.56	1.8×10^{-4}
E.Coli substrate graph	282	2.9	3.04	0.32	0.026
C.Elegans	282	2.65	2.25	0.28	0.05

Small world phenomenon: Watts/Strogatz model

Reconciling two observations:

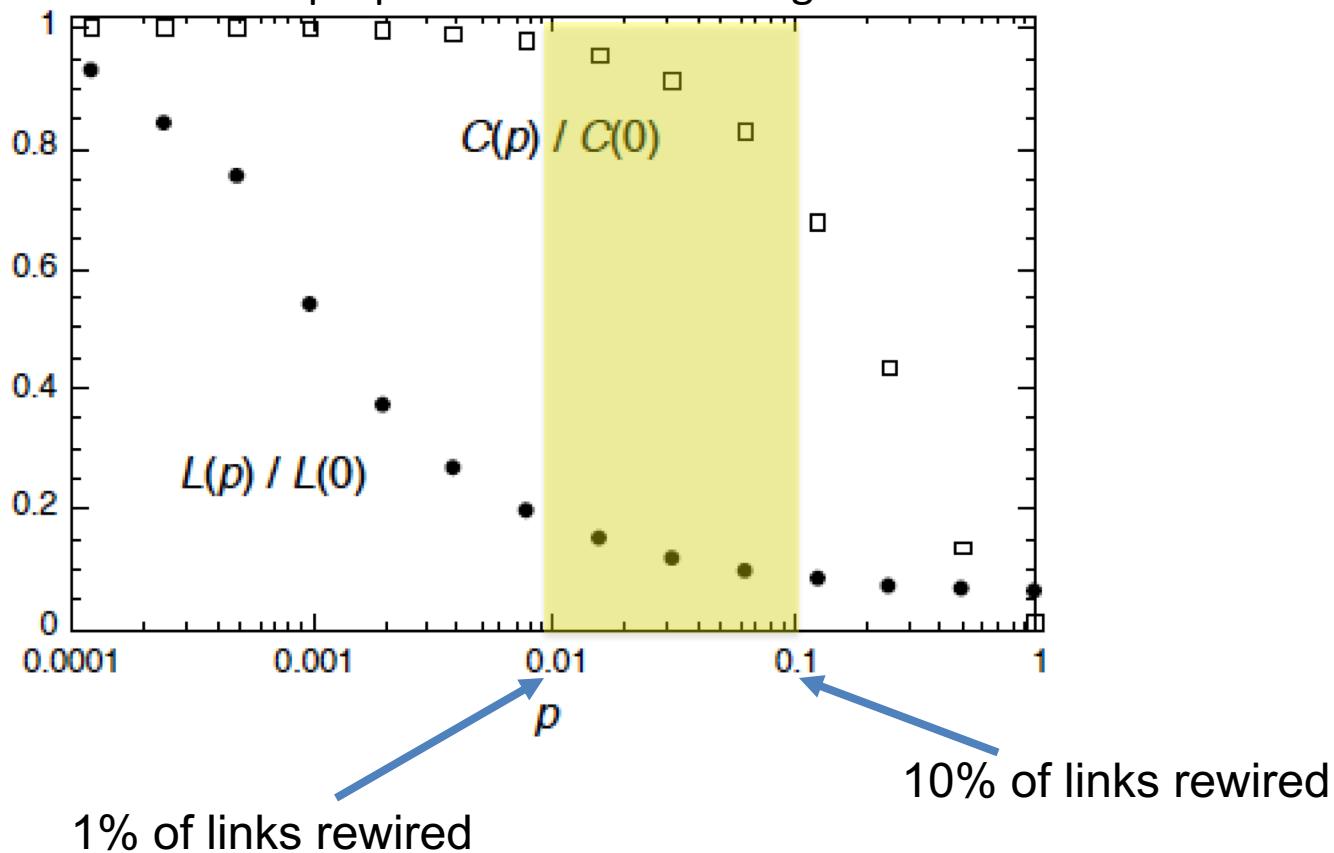

- **High clustering:** my friends' friends tend to be my friends
- **Short average paths**

Watts-Strogatz model: Generating small world graphs

- Each node has $K \geq 4$ nearest neighbors (local)
- tunable: vary the probability p of rewiring any given edge
- small p : regular lattice
- large p : classical random graph

Watts/Strogatz model:
Change in clustering coefficient and average path length as a function of the
proportion of rewired edges

Between 1% and 10% rewired the shortest path decreases and the C stays high!!

Definition of Clustering Coefficient

`clustering(G, nodes=None, weight=None)` [source]

Compute the clustering coefficient for nodes.

For unweighted graphs, the clustering of a node u is the fraction of possible triangles through that node that exist,

$$c_u = \frac{2T(u)}{\deg(u)(\deg(u) - 1)},$$

where $T(u)$ is the number of triangles through node u and $\deg(u)$ is the degree of u .

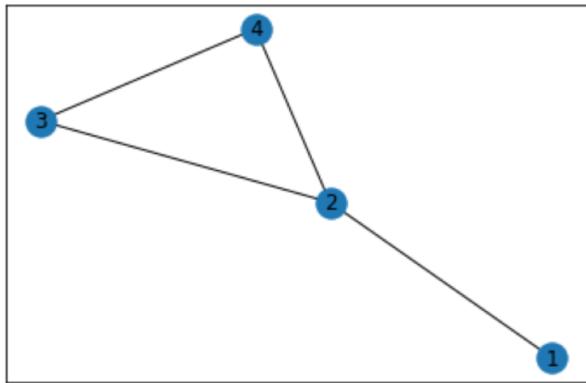

Note there are extensions of the definitions for Weighted and Directed Graphs

Next class we study the calculations of Paths and clustering coefficient in ipynb and cover Routing in Networks

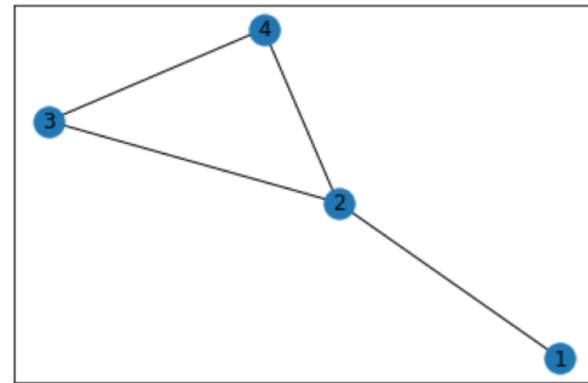

In the social sciences, the word "**clique**" is used to describe a group of 2 to 12 (averaging 5 or 6) "persons who interact with each other more regularly and intensely than others in the same setting."

Example 1 Average Clustering Coefficient

Example 1, Average Shortest Path

For Monday 02/08

- Finalize Problem 1 Assignment 1
- Optional: Read article uploaded in Lecture 3, answer Participation Slides 3

Lecture 3 Class Lab

Community structure and ethnic preferences in school
friendship networks

Reading_SocialNetwork.ipynb

SchoolEdges.csv

SchoolNodes.csv

Data and Article uploaded in Lecture 3 folder

In `ReadingSocialNetwork.ipynb` we analyze the Results of a School Survey

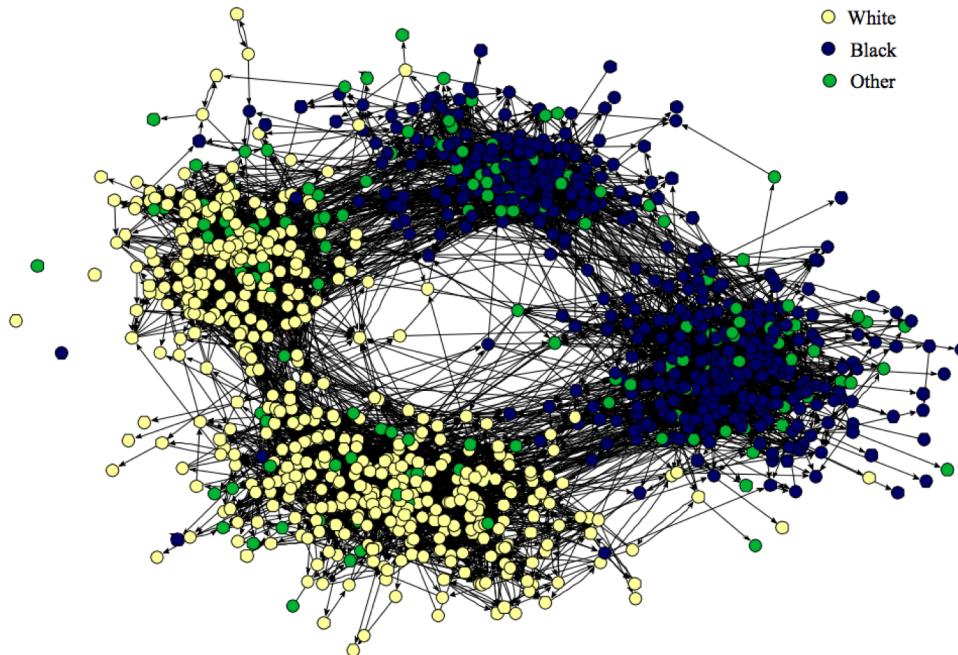

Fig. 3.4 Friendship network of children in a U.S. school. Friendships are determined by asking the participants, and hence are directed, since A may say that B is their friend but not vice versa. Vertices are color coded according to race, as marked, and the split from left to right in the figure is clearly primarily along lines of race. The split from top to bottom is between middle school and high school, i.e., between younger and older children. Picture courtesy of James Moody.

Lab (Group Exercise)

For the 4 nodes network MyFirstNwtwork.ipynb, report:

- 1- Calculate the Clustering Coefficient of each node and of the network
- 2- Calculate the Clustering Coefficient of of the network
- 3-Calculate the average shortest path of the network

(you can verify the answers of slides 16 and 17)

Software for complex networks

NetworkX is a Python package for the creation,
manipulation, and study of the structure, dy-
namics, and functions of complex networks.
